Please go to the downloads page on the website for information about them. Most plants, such as trees, shrubs, and seedlings, require a continuous supply of water from the soil to obtain a healthy growth. It is difficult to provide sufficient water to these plants, and to all roots, in winter time and during the dry summer. This is especially difficult with trees and shrubs which are planted deep in the ground and do not have the surface roots of a grass plant. In arid regions, especially, these plants often perish from drought in the wintertime. In a like manner, those parts of plants growing in a deep root zone have also been noted to not receive the necessary air-water exchange during the dry summer months. In order to maintain a healthy growth of a plant, water must be delivered to all parts of the plant and excess water must be drained from the plant. The use of a simple drain pipe, which is extended from the plant's roots upwardly into the soil, will not provide for the needed air-water exchange. In the winter time, the soil will be dry and will have little moisture content. Water delivered to the root area of the plant will evaporate quickly and will be drawn from the surface of the ground. With the soil having little moisture, it will not retain the water delivered and will drain through the pipes and into the ground. To overcome this problem, various efforts have been made to attempt to provide a suitable moisture-retaining means. For example, the use of one or more pairs of upwardly extending pipes have been used to deliver water to the root of a plant, and to retain the water in the pipes to be delivered to the roots. Such efforts have met with only limited success. The liquid trapped in the pipes can collect together and block the flow of water, thus preventing the plant from receiving the needed water. Other efforts have utilized various types of collapsible inserts which are placed in the upper ends of the pipes. These inserts prevent the pipes from being completely blocked by the water collecting in the pipes. Those attempts that have been made have not resulted in the creation of a water retaining device which not only retains the water while delivering it to the roots of the plant, but which also dries the root zone of the plant and prevents water that is delivered to the root zone from evaporating and being lost to the ground. Examples of various types of liquid retaining or drainage devices are shown in the following U.S. Pat. Nos.: _____ U.S. Pat. No. Inventor(s)
